Feature List - Intershop Progressive Web App 12.1.0

Release 12.1.0 of the Intershop Progressive Web App comes with huge SEO and B2B e-commerce features. Users responsively in a cohesive application with a unified look and feel thanks to the dedication for building a single-page application. Users can easily find products with the powerful search and navigation capabilities. Customers can buy products in a fast and convenient way by quoting, cost center, and a Buy&Approve use case easily meet the reporting requirements that apply to most B2B companies.

See the features of the current release in the **Guide**.

Please note that features and options depicted as Roadmap are currently marked as "additional options".

Benefits for Customers	Benefits for Companies	Benefits for Developers
Smooth and responsive customer experience. The applied JavaScript to mobile devices and browsers boosts the performance. Customers can easily find products with powerful search and navigation. Most of the pages is much shorter. With data caching and prefetching, the time to load pages is reduced. Customers can buy products in a fast and convenient way by quoting, cost center, and a Buy&Approve use case easily meet the reporting requirements that apply to most B2B companies.	The digital world is developing rapidly. Mobile technologies, new end devices, and search-power-ups are the possibilities for companies to inspire their customers. Intershop's Progressive Web App is, therefore, worth switching to and investing in. Intershop's Progressive Web App is the first step towards digital success. The only prerequisite for the Intershop Progressive Web App is a powerful backend. Leading-edge UI technology and a high-performance programming environment and operating system.	By using widely accepted technologies such as JavaScript, HTML5, and CSS, the build-in-fast-starting, single-page application Intershop Progressive Web App is easy to extend and customize for your clients.

2. Experience Management

2.1. Intershop Progressive Web Application	
Toolset	Web Developers can use the Intershop PWA to implement storefront applications based on the Intershop Commerce Management (ICM) Headless REST API and/or 3rd Party Systems.
Templates	Templates contain the HTML that is rendered for the browser and displays the UI.
Services	Services are used to encapsulate and provide data from the backend systems. A single responsibility is encapsulated in each service that has access to the backend. A service should do as little as possible because services are used throughout the application. Services are implemented independently of multiple services and can be exchanged at runtime if necessary.
Components	Components are small and strictly independent bridges between services and templates/pages. Components are used to implement a single piece of the UI and to interact with services. Only those things that are directly needed for a piece of UI are provided from the component.
	The components handling the templates should only handle rearrangement and should not contain any business logic. Components should not be used to fetch data from a backend providing data for the templates. It might be necessary to extend the data received.
	Multiple components and their templates can be composed to pages.
Routes	Routes handle navigation between pages. Routes are used to perform application navigation. Routes are configured in a declarative way. Routes can be configured in a way that they execute page specific code/work to prepare.
Modals	Modals are dictionaries of the data that are needed for the application.
Store	The store is the central representation of all data in the application.
	The state is seen as the single source of truth for getting information of the current application state. All information should be held in the store. There is only one instance of the store in the application. Components, services, and effects can access the store. Components should not read the state directly. Selectors are used to read data from the store.
Selectors	Selectors are used to retrieve information about the current state from the store. The selectors are grouped in segments. The first segment starts from the query from the root of the state tree and navigates to the required information. Selectors return observables that emit every time the value of the selected state changes.
Actions	Actions are used to alter the current state of the application through reducers. Action creators are held in segments like the selectors. Action creators contain a type of the action and a payload with the data that is needed to alter the state. Actions are dispatched to alter the state and to trigger effects.
Reducers	Reducers alter the state synchronously. They take the previous state and an incoming action and calculate the next state. The reducers are implemented in segments. Each component, each functionality has its own reducer/segment. Reducers should be simple operations which are easily testable.
Effects	Effects are used to perform tasks that are not pure functions where the opening MDT (Monitor, Debug, Inspect) is triggered. Effects perform asynchronous tasks and trigger actions as a way to alter the current state of the application.
Externalize	Externalize allows the easy creation of code artifacts that automatically compile to the configuring platform of the project, using a list of files for repetitive tasks and increasing productivity.
Localization	Intershop Progressive Web App uses angular's internationalization tools. Ofnik and the npm module ngx-translate-extract library for localization.
	Intershop Progressive Web App supports the translation of texts, numbers, dates, timedelta, and relative dates. Intershop Progressive Web App supports the translation of texts with ICU-Syntax, e.g. multiple language. Texts can be translated using the configured dictionary for the current user agents. E.g. texts in German are displayed to a German user.
Integrated Content Management	Content managed in Intershop Commerce Management can be integrated into the storefront application. Content pages, product descriptions, and category texts can be rendered into the storefront and edited directly in the Intershop Commerce Management.
Deployment Scripts	Templates for Kubernetes Deployments and DevOps for Microsoft Azure are supplied as part of the project.
Themes	Themes allow to adapt the appearance of the shop.
	Data formats can be modified in the form of configurable themes can be modified as variables. Multiple theme (color, and/or configurable) can be combined.
2.2. Functional Scope	
Storefront	The Intershop Progressive Web App is an essential component of Intershop's new cloud offering. It is the UI for the Intershop Commerce Management (ICM) REST API. The Intershop Progressive Web App supports all the functions of an easily-defined B2B e-commerce storefront. Intershop's Progressive Web App is the first step towards digital success. The only prerequisite for the Intershop Progressive Web App is a powerful backend. Leading-edge UI technology and a high-performance programming environment and operating system.
Responsibility	The Intershop Progressive Web App meets the WCAG 2.1 AA accessibility standards.
Shopping Experience	
Catalog Browsing	Customers can browse categories by different means, like category navigation, searching, and filtering.
Product Browsing	Products can be browsed by using a search and filtered by search filters (supported filter types are checkboxes and single or multi-select checkbox). Product lists support endless scrolling. Product lists can be sorted by different criteria (e.g. alphabetical, prices, etc.).
	Property can choose between a paged or endless scrolling product list.
Search	Standard search (one full text field).
	Customers can search products by SKU or search terms found in the product name, description, or any other attribute that is indexed in the search index. Suggested search is provided while typing search terms. Search results are displayed in a product list. Advanced suggest search shows matching search terms, product categories, and products. Search terms can be highlighted in the search results.
	Search results should also be used within the storefront.
	SPARQUE search (additional option)
	Customers can search products by SKU or any attribute that is present in the search index. Search results are displayed in a product list.
	Advanced suggest search shows matching search terms, product categories, and products. Search terms can be highlighted in the search results.
Product Display & Actions	The following product data can be displayed:
	• Multiple product images, including product zoom • Product prices • Inventory • Description • Product attributes • Product Sales Ideas, Top Seller, Sales • Product ratings • Product attachments • Product reviews • Product bundle parts
	The following actions can be performed with products:
	• Add to cart • Add to compare list • Add to quote • Add to wishlist • Add to order template • Share via e-mail • E-mail a friend • Print product page • Product notification for in stock and price
Product Variations	Products with different variations are displayed on product lists, product detail pages, and in the shopping cart. Variations can be color, size, or any other characteristic that is supported and displayed. Joseph Category Filter, color, size and other combinations. Advanced variation handling for complex products with a set of variations can be configured in the Intershop Commerce Management. The Intershop Progressive Web App types number and combine values of variation attributes are supported.
Product Bundles	Product bundles with all related bundled products are displayed on product detail pages and in the shopping cart.
Retail Sets	Retail sets with all related items are displayed on product detail pages and can be added to the shopping cart.
Personalized Product and Category Rank	Category, products, and product attributes are displayed in a personalized way for the current user.
Scaled Prices	Scaled prices are displayed on product lists, product detail pages, product compare pages, and quick BUILD, and can be displayed in the shopping cart and during the checkout process.
	Related products of a certain product are displayed on product detail pages. The following types are supported:
